

OpenCL (Open Computing Language) is a multi-vendor open standard for general-purpose parallel programming of heterogeneous systems that include CPUs, GPUs, and other processors. OpenCL provides a uniform programming environment for software developers to write efficient, portable code for high-performance compute servers, desktop computer systems, and handheld devices.

Specification documents and online reference are available at www.khronos.org/opencvl.

OpenCL Class Diagram

The figure below describes the OpenCL specification as a class diagram using the Unified Modeling Language¹ (UML) notation. The diagram shows both nodes and edges which are classes and their relationships. As a simplification it shows only classes, and no attributes or operations.

¹ Unified Modeling Language (<http://www.uml.org/>) is a trademark of Object Management Group (OMG).

OpenCL Device Architecture Diagram

The table below shows memory regions with allocation and memory access capabilities. R=Read, W=Write

	Host	Kernel
Global	Dynamic allocation R/W access	No allocation R/W access
Constant	Dynamic allocation R/W access	Static allocation R-only access
Local	Dynamic allocation No access	Static allocation R/W access
Private	No allocation No access	Static allocation R/W access

The conceptual OpenCL device architecture diagram shows processing elements (PE), compute units (CU), and devices. The host is not shown.

Conversions and Type Casting Examples [6.2]

Memory Model: Shared Virtual Memory [3.3.3]

OpenCL extends the global memory region into the host memory region through a shared virtual memory (SVM) mechanism. There are three types of SVM in OpenCL

- **Coarse-Grained buffer SVM:** Sharing occurs at the granularity of regions of OpenCL buffer memory objects. Consistency is enforced at synchronization points and with map/unmap commands to drive updates between the host and the device. This form of SVM is similar to the use of `cl_mem` buffers, with two differences. First, it lets kernel-instances share pointer-based data structures (such as linked-lists) with the host program. Second, concurrent access by multiple kernels on the same device is valid as long as the set of concurrently executing kernels is bounded by synchronization points. Concurrent access by multiple kernels on the same device is valid as long as the set of kernels is bounded by synchronization points. This form of SVM is similar to non-SVM use of memory; however, it lets kernel-instances share pointer-based data structures (such as linked-lists) with the host program. Program scope global variables are treated as per-device coarse-grained SVM for addressing and sharing purposes.

- **Fine-Grained buffer SVM:** Sharing occurs at the granularity of individual loads/stores into bytes within OpenCL buffer memory objects. Loads and stores may be cached. This means consistency is guaranteed at synchronization points. If the optional OpenCL atomics are supported, they can be used to provide fine-grained control of memory consistency.
- **Fine-Grained system SVM:** Sharing occurs at the granularity of individual loads/stores into bytes occurring anywhere within the host memory. Loads and stores may be cached so consistency is guaranteed at synchronization points. If the optional OpenCL atomics are supported, they can be used to provide fine-grained control of memory consistency.

Coarse-Grained buffer SVM is required in the core OpenCL specification. The two finer grained approaches are optional features in OpenCL. The various SVM mechanisms to access host memory from the work-items associated with a kernel instance are summarized in table 3-2 below.

Summary of SVM Options in OpenCL [3.3.3, Table 3-2]

SVM	Granularity of sharing	Memory allocation	Mechanisms to enforce consistency	Explicit updates between host and device?
Non-SVM buffers	OpenCL Memory objects (buffer)	<code>clCreateBuffer</code>	Host synchronization points on the same or between devices.	Yes, through Map and Unmap commands.
Coarse-Grained buffer SVM	OpenCL Memory objects (buffer)	<code>clSVMAlloc</code>	Host synchronization points between devices	Yes, through Map and Unmap commands.
Fine Grained buffer SVM	Bytes within OpenCL Memory objects (buffer)	<code>clSVMAlloc</code>	Synchronization points plus atomics (if supported)	No
Fine-Grained system SVM	Bytes within Host memory (system)	Host memory allocation mechanisms (e.g. malloc)	Synchronization points plus atomics (if supported)	No

Atomic Functions [6.13.11]

OpenCL C implements a subset of the C11 atomics (see section 7.17 of the C11 specification) and synchronization operations.

In the following tables, **A** refers to an atomic_* type (not including atomic_flag). **C** refers to its corresponding non-atomic type. **M** refers to the type of the other argument for arithmetic operations. For atomic integer types, **M** is C. For atomic pointer types, **M** is ptrdiff_t.

The type atomic_* is a 32-bit integer. `atomic_long` and `atomic_ulong` require extension `cl_khr_int64_base_atomics` or `cl_khr_int64_extended_atomics`. The `atomic_double` type requires double precision support. The default scope is `work_group` for local atomics and all_svm_devices for global atomics. The extensions `cl_khr_int64_base_atomics` and `cl_khr_int64_extended_atomics` implement atomic operations on 64-bit signed and unsigned integers to locations in __global and __local memory.

See the table under Atomic Types and Enum Constants for information about parameter types memory_order, memory_scope, and memory_flag.

Enqueuing and Kernel Query Built-in Functions [6.13.17] [9.17.3.6]

A kernel may enqueue code represented by Block syntax, and control execution order with event dependencies including user events and markers. There are several advantages to using the Block syntax: it is more compact; it does not require a cl_kernel object; and enqueueing can be done as a single semantic step. Sub-groups require the **cl_khr_subgroups** extension. The macro CLK_NULL_EVENT refers to an invalid device event. The macro CLK_NULL_QUEUE refers to an invalid device queue.

```
int enqueue_kernel (queue_t queue, kernel_enqueue_flags_t flags,
const ndrange_t ndrange, void (^block)(void))
int enqueue_kernel (queue_t queue, kernel_enqueue_flags_t flags,
const ndrange_t ndrange, uint num_events_in_wait_list,
const clk_event_t *event_wait_list, clk_event_t *event_ret,
void (^block)(void))
int enqueue_kernel (queue_t queue, kernel_enqueue_flags_t flags,
const ndrange_t ndrange,
void (^block)(local void *, ...), uint size0, ...)
int enqueue_kernel (queue_t queue, kernel_enqueue_flags_t flags,
const ndrange_t ndrange,
uint num_events_in_wait_list, const clk_event_t *event_wait_list,
clk_event_t *event_ret, void (^block)(local void *, ...), uint size0, ...)
```

Allows a work-item to enqueue a block for execution to *queue*. Work-items can enqueue multiple blocks to a device queue(s).
flags may be one of
CLK_ENQUEUE_FLAGS_
{NO_WAIT, WAIT_KERNEL,
WAIT_WORK_GROUP}

uint get_kernel_work_group_size (void (^ <i>block</i>)(void))	Query the maximum work-group size that can be used to execute a block.
uint get_kernel_work_group_size (void (^ <i>block</i>)(local void *, ...))	
uint get_kernel_preferred_work_group_size_multiple (void (^ <i>block</i>)(void))	Returns the preferred multiple of work-group size for launch.
uint get_kernel_preferred_work_group_size_multiple (void (^ <i>block</i>)(local void *, ...))	
int enqueue_marker (queue_t <i>queue</i> , uint <i>num_events_in_wait_list</i> , const clk_event_t * <i>event_wait_list</i> , clk_event_t * <i>event_ret</i>)	Enqueue a marker command to <i>queue</i> .
uint get_kernel_sub_group_count_for_ndrange (const ndrange_t <i>ndrange</i> , void (^ <i>block</i>)(void))	Returns number of subgroups in each workgroup of the dispatch.
uint get_kernel_sub_group_count_for_ndrange (const ndrange_t <i>ndrange</i> , void (^ <i>block</i>)(local void *, ...))	
uint get_kernel_max_sub_group_size_for_ndrange (const ndrange_t <i>ndrange</i> , void (^ <i>block</i>)(void))	Returns the maximum sub-group size for a block.
uint get_kernel_max_sub_group_size_for_ndrange (const ndrange_t <i>ndrange</i> , void (^ <i>block</i>)(local void *, ...))

Notes

Image Read and Write Functions [6.13.14]

The built-in functions defined in this section can only be used with image memory objects created with `clCreateImage`. *sampler* specifies the addressing and filtering mode to use. *aQual* refers to one of the access qualifiers. For samplerless read functions this may be `read_only` or `read_write`.

- Writes to images with sRGB channel orders requires device support of the `cl_khr_srgb_image_writes` extension.
- `read_imageh` and `write_imageh` require the `cl_khr_fp16` extension.
- MSAA images require the `cl_khr_gl_msaa_sharing` extension.
- Image 3D writes require the extension `cl_khr_3d_image_writes`. [9.4.8]

  <normalized-mode> | <address-mode> | <filter-mode>
```

normalized-mode:

```

OpenCL Extensions Reference

Section and table references are to the OpenCL Extensions 2.1 specification.

Using OpenCL Extensions [9]

The following extensions extend the OpenCL API. Extensions shown in *italics* provide core features.

To control an extension: `#pragma OPENCL EXTENSION extension_name : {enable | disable}`

To test if an extension is supported, use `clGetPlatformInfo()` or `clGetDeviceInfo()`

To get the address of the extension function: `clGetExtensionFunctionAddressForPlatform()`

Example of Enqueuing Kernels

Arguments that are a pointer type to local address space [6.13.17.2]

A block passed to `enqueue_kernel` can have arguments declared to be a pointer to local memory. The `enqueue_kernel` built-in function variants allow blocks to be enqueued with a variable number of arguments. Each argument must be declared to be a void pointer to local memory. These `enqueue_kernel` built-in function variants also have a corresponding number of arguments each of type `uint` that follow the block argument. These arguments specify the size of each local memory pointer argument of the enqueued block.

```
kernel void
my_func_A_local_arg1(global int *a, local int *lptr, ...)
{
    ...
}

kernel void
my_func_A_local_arg2(global int *a,
    local int *lptr1, local float4 *lptr2, ...)
{
    ...
}

kernel void
my_func_B(global int *a, ...)
{
    ...
    ndrange_t ndrange = ndrange_1d(...);
    uint local_mem_size = compute_local_mem_size();
    enqueue_kernel(get_default_queue(),
        CLK_ENQUEUE_FLAGS_WAIT_KERNEL,
        ndrange,
        ^(local void *p){
            my_func_A_local_arg1(a, (local int *)p, ...));
        },
        local_mem_size);
}

kernel void
my_func_C(global int *a, ...)
{
    ...
    ndrange_t ndrange = ndrange_1d(...);
    void (^my_blk_A)(local void *, local void *) =
        ^(local void *lptr1, local void *lptr2){
            my_func_A_local_arg2(
                a,
                (local int *)lptr1,
                (local float4 *)lptr2, ...));
    // calculate local memory size for lptr
    // argument in local address space for my_blk_A
    uint local_mem_size = compute_local_mem_size();
    enqueue_kernel(get_default_queue(),
        CLK_ENQUEUE_FLAGS_WAIT_KERNEL,
        ndrange,
        my_blk_A,
        local_mem_size, local_mem_size * 4);
}
```

A Complete Example [6.13.17.3]

The example below shows how to implement an iterative algorithm where the host enqueues the first instance of the nd-range kernel (`dp_func_A`). The kernel `dp_func_A` will launch a kernel (`evaluate_dp_work_A`) that will determine if new nd-range work needs to be performed. If new nd-range work does need to be performed, then `evaluate_dp_work_A` will enqueue a new instance of `dp_func_A`. This process is repeated until all the work is completed.

```
kernel void
dp_func_A(queue_t q, ...)
{
    ...
    // queue a single instance of evaluate_dp_work_A to
    // device queue q. queued kernel begins execution after
    // kernel dp_func_A finishes

    if (get_global_id(0) == 0)
    {
        enqueue_kernel(q,
            CLK_ENQUEUE_FLAGS_WAIT_KERNEL,
            ndrange_1d(1),
            ^{evaluate_dp_work_A(q, ...)});
    }
}

kernel void
evaluate_dp_work_A(queue_t q,...)
{
    // check if more work needs to be performed
    bool more_work = check_new_work(...);
    if (more_work)
    {
        size_t global_work_size = compute_global_size(...);
        void (^dp_func_A_blk)(void) =
            ^{dp_func_A(q, ...)};

        // get local WG-size for kernel dp_func_A
        size_t local_work_size =
            get_kernel_work_group_size(dp_func_A_blk);

        // build nd-range descriptor
        ndrange_t ndrange = ndrange_1D(global_work_size,
            local_work_size);

        // enqueue dp_func_A
        enqueue_kernel(q,
            CLK_ENQUEUE_FLAGS_WAIT_KERNEL,
            ndrange,
            dp_func_A_blk);
    }
    ...
}
```
